

A Stringy Origin of M2 Brane Chern-Simons Theories

Mina Aganagic

Center for Theoretical Physics, University of California, Berkeley, CA 94720

We show that string duality relates M-theory on a local Calabi-Yau fourfold singularity X_4 to type IIA string theory on a Calabi-Yau threefold X_3 fibered over a real line, with RR 2-form fluxes turned on. The RR flux encodes how the M-theory circle is fibered over the IIA geometry. The theories on N D2 branes probing X_3 are the well-known quiver theories with $\mathcal{N} = 2$ supersymmetry in three dimensions. We show that turning on fluxes, and fibering the X_3 over a direction transverse to the branes, corresponds to turning on $\mathcal{N} = 2$ Chern-Simons couplings. String duality implies that, in the strong coupling limit, the N D2 branes on X_3 in this background become N M2 branes on X_4 . This provides a string theory derivation for the recently conjectured description of the M2 brane theories on Calabi-Yau fourfolds in terms of $\mathcal{N} = 2$ quiver Chern-Simons theories. We also provide a new $\mathcal{N} = 2$ Chern-Simons theory dual to $AdS_4 \times Q^{1,1,1}$. Type IIA/M-theory duality also relates IIA string theory on X_3 with only the RR fluxes turned on, to M-theory on a G_2 holonomy manifold. We show that this implies that the N M2 branes probing the G_2 manifold are described by the quiver Chern-Simons theory originating from the D2 branes probing X_3 , except that now Chern-Simons terms preserve only $\mathcal{N} = 1$ supersymmetry in three dimensions.

1. Introduction

Duality provides powerful tools to understand string theory. AdS/CFT correspondence defines quantum gravity in AdS backgrounds in terms of the dual conformal field theory. At the same time, gravity on AdS space describes the conformal theory at large N . Similarly IIA/M-theory duality provides a way to understand the strong coupling limit of type IIA string theory in terms of 11 dimensional supergravity. Conversely, in compactifications of M-theory on a circle, IIA string theory defines the still mysterious quantum theory that underlies M-theory.

One of the mysteries of M-theory is how to describe the theory on N coincident M2 branes. At low energies, this should be the conformal field theory dual to M-theory on $AdS_4 \times M_7$ where M_7 is seven dimensional Einstein manifold [1]. The theories on N M2 branes in M-theory are dual to the theory on N D2 branes in IIA. The latter theory is a gauge theory, with the dimensionfull coupling constant proportional to g_s . In the strong coupling limit, the D2 brane theory should describe M2 branes. However, the resulting theory is apparently always strongly coupled, so the description does not seem useful

A way around this was proposed in [2]. The idea is that, at low energies, the theory on the M2 branes may be a Chern-Simons theory, with matter. The Chern-Simons level provides a dimensionless coupling constant needed to define the gauge theory. Moreover, Chern-Simons interaction is scale invariant, being independent of the metric, so the theory could also be conformal. Recently, [3] constructed a Chern-Simons theory corresponding to N M2 branes on Calabi-Yau fourfold $X_4 = \mathbf{C}^4/\mathbf{Z}_k$, where k gets identified with the level. This theory is conformal, and dual, at large N to M-theory on $AdS_4 \times S^7/\mathbf{Z}_k$. Moreover, for $k = 1$ it should correspond to M2 branes on flat space, with maximal supersymmetry in three dimensions. Various authors [4,5,6,7,8] proposed generalizations of this construction to Chern-Simons theories describing M2 branes on local Calabi-Yau fourfolds. A check of these proposals is that for a single M2 brane, the moduli space is indeed the Calabi-Yau fourfold X_4 . However, in general, there is more than one such Chern-Simons theory that one can write down which would still give the same moduli space [9,10,11]. It is possible that there are dualities relating some of these theories, but we cannot a-priori exclude that they flow to different theories at long distance.

The aim of this paper is to provide a stringy derivation of the Chern-Simons theory on N M2 branes probing a local Calabi-Yau fourfold X_4 ¹. To begin with, we show that, M-theory on a local toric Calabi-Yau fourfold X_4 is dual to IIA string theory on a Calabi-Yau threefold X_3 fibered over $\mathbf{R}$. The Kahler moduli of X_3 vary over $\mathbf{R}$ and moreover, there are RR 2-form fluxes on $X_3 \times \mathbf{R}$. This is a consequence of a purely geometrical observation: The toric Calabi-Yau fourfold X_4 is a circle fibration over $X_3 \times \mathbf{R}$. Moreover, the viewing the coordinate on the S^1 as a section of a $U(1)$ bundle on $X_3 \times \mathbf{R}$ the curvature of the corresponding connection is easy to compute. When we compactify M-theory on X_4 , the IIA/M theory duality relates it to IIA on $X_3 \times \mathbf{R}$, where the curvature of the $U(1)$ bundle gets identified with the RR 2-form flux in IIA.

The theory on N D2 branes in IIA probing the local Calabi-Yau threefold X_3 is well known, in the limit where X_3 develops a singularity. These are $\mathcal{N} = 2$ quiver gauge theories in three dimensions, with superpotential. More precisely, the theories on Dp branes probing X_3 were studied extensively for D3 branes and D0 branes². However, given X_3 , the theories on N D-branes probing it are the same, at least classically, in any dimension – differing only by compactifications on tori, and dimensional reduction. This is because the theory on the branes is determined by internal CFT on a disk – and the answers can be formulated in terms of the geometry of X_3 and fractional branes wrapping it.

Next, we consider deforming the theory by turning on RR fluxes and fibering X_3 over $\mathbf{R}$, so that the type IIA string theory becomes dual to M-theory on a local Calabi-Yau fourfold singularity X_4 . On the one hand, the deformation has to preserve $\mathcal{N} = 2$ supersymmetry on the D2 brane world volume, since the theory lifts to M2 branes on

¹ Such a derivation was proposed in [3,6] for the theories studied there. While the string realizations are dual to each other, our proposal is simpler, and the relevant string backgrounds are better understood. Moreover, we provide a unified derivation, applicable for a large class of toric Calabi-Yau singularities.

² The former were studied as examples of conformal field theories in four dimensions with four supercharges (see for example [12][13][14][15]) while the latter were studied in the context of 4d $\mathcal{N} = 2$ black holes (see for example, [16][17]). Detailed derivation of the quiver theory from mirror symmetry [18] and the classical geometry of intersecting three-cycles was presented in [12]. An alternative derivation was developed in [19] and many followup works, starting from the theories of branes on orbifolds $\mathbf{C}^3/\mathbf{Z}_k \times \mathbf{Z}_m$, which have a free worldsheet CFT description and following their deformations.

the Calabi-Yau fourfold. On the other hand, turning on RR fluxes on X_3 corresponds to turning on Chern-Simons couplings in the gauge theory. Namely, at the Calabi-Yau singularity, the D2 branes split into fractional branes, wrapped on the vanishing cycles. The Wess-Zumino terms on the brane world-volume, in the presence of RR flux, induce Chern-Simons couplings in three dimensions. By supersymmetry then, these become the $\mathcal{N} = 2$ preserving Chern-Simons terms. This is exactly what is needed to describe D2 branes on X_3 fibered over $\mathbf{R}$. Namely, $\mathcal{N} = 2$ Chern-Simons terms imply that Fayet-Iliopoulos terms vary as a function of the real scalar field in the $\mathcal{N} = 2$ vector multiplet. The later parameterizes the direction in $\mathbf{R}^{3,1}$ transverse to the D2 branes. Since Fayet-Iliopoulos terms in the gauge theory correspond to Kahler moduli in the Calabi-Yau, this is exactly what is needed to describe N D2 branes on X_3 fibered over $\mathbf{R}$.

Consequently, string duality implies that $\mathcal{N} = 2$ quiver theory on N D2 branes probing X_3 , with $\mathcal{N} = 2$ Chern-Simons terms turned on lifts to the theory on N M2 branes probing X_4 . At strong coupling, the gauge kinetic terms vanish, and the theory becomes a Chern-Simons quiver theory. These are precisely the theories proposed in [3,6,4,5,7,8] to describe N M2 branes on various local Calabi-Yau fourfold singularities. The relation to the theories on the D3 branes probing X_3 was noticed there, but its physical meaning was missed. As mentioned above, one test of the proposals in the literature is that the moduli space of a single M2 brane should be X_4 . What we are proposing here is stronger, since the theories on D2 branes probing $X_3 \times \mathbf{R}$, with fluxes, can be *derived from string theory*, as we explained. This should be contrasted with the theories "without 4d parents" in [11,9,10]³.

It is natural to expect that the quiver Chern-Simons theory of X_4 we wrote down is a conformal field theory in three dimensions. This has already been shown in cases studied in [3,6]. It should hold more generally, since on general grounds, local Calabi-Yau fourfold singularities X_4 's should be cones over Einstein-Sasaki 7-manifolds Y_7 [21]. We have shown that the quiver Chern-Simons theory describes N M2 branes at the tip of this cone. In the near horizon limit, the branes deform the geometry to $AdS_4 \times Y_7$, so at least in the large N limit, the conformal symmetry of the theory is manifest⁴.

Finally, similar ideas can be used to find the theories on N M2 branes probing local G_2 holonomy manifolds⁵. Namely IIA/M-theory duality relates IIA on a Calabi-Yau threefold

³ Some of these theories do pass some stringent tests. See for example [20], [10].

⁴ The cases where the explicit cone metrics are known are limited. See for example [22] and references therein.

⁵ The Chern-Simons theories on 1 M2 brane probing a local G_2 holonomy manifold were first discovered in [23].

X_3 with RR fluxes turned on, to M-theory on a G_2 holonomy manifold. Turning on fluxes in this case corresponds to deforming the $\mathcal{N} = 2$ quiver gauge theories on N D2 branes probing X_3 by $\mathcal{N} = 1$ Chern-Simons terms. At low energies, these theories become the theories on N M2 branes on the corresponding G_2 holonomy manifolds. Since the gauge kinetic terms vanish in this limit, the theories describing the M2 branes are $\mathcal{N} = 1$ quiver Chern-Simons theories. We do not expect these theories to be conformal, as $G_2 \times \mathbf{R}$ is not a cone, and no corresponding Einstein 7-manifolds are known [21].

The paper is organized as follows. In section 2 we show that a toric Calabi-Yau fourfold can be thought of as a circle fibration over $X_3 \times \mathbf{R}$. We show how to find the first Chern class of the fibration. This implies that M-theory compactified on X_4 is dual to IIA on $X_3 \times \mathbf{R}$ with fluxes turned on. In section 3 we derive from string theory the theories on N D2 branes probing X_3 , in these backgrounds. For one brane, we show that the moduli space becomes X_4 , similarly to [5,7,24]. Moreover, X_4 is fibered over $X_3 \times \mathbf{R}$ in a manner consistent with the Chern-Simons terms turned on. Namely, in IIA/M-theory duality the center of mass $U(1)$ gauge field on the D2 brane is dual, via scalar vector duality in three dimensions, to the compact scalar field parameterizing the M2 brane position on the M-theory circle. We will show that in the presence of Chern-Simons terms, this scalar picks up a charge. This has the interpretation of having the M-theory circle be fibered non-trivially over X_3 . Moreover, we will show that the Chern class of this fibration, is precisely such to correspond to RR 2-form fluxes that generated the Chern-Simons terms on the D2 brane in the first place. In sections 4-8 we give some examples. The examples of sections 4-7 have already appeared in literature. We are providing a string theory derivation of the corresponding Chern-Simons quiver theories and an interpretation, in the context of IIA/M-theory duality. The example in section 8 is new, providing a new quiver Chern-Simons theory that should be dual, based on IIA/M-theory duality to N M2 branes on a cone over $Q^{1,1,1}$.⁶ Finally, in section 9 we use IIA/M-theory duality to derive the $\mathcal{N} = 1$ quiver Chern-Simons theories on M2 branes probing local G_2 holonomy manifolds.

2. Calabi-Yau Fourfolds and M-theory/IIA duality

In this section from purely geometric considerations, we will derive a duality between M-theory compactification on a Calabi-Yau fourfold X_4 and type IIA on a Calabi-Yau

⁶ This theory was discussed recently in [25], but this connection was not made.

threefold X_3 fibered over a real line $\mathbf{R}$, with fluxes turned on. Namely, we will show here that a Calabi-Yau fourfold X_4 can be described as a circle fibration over a base. The base is a Calabi-Yau 3-fold X_3 fibered over a real line $\mathbf{R}$. The first Chern Class of the circle fibration is typically non-vanishing. This implies that when we compactify M-theory on X_4 , there will be RR 2-form fluxes turned on, on $X_3 \times \mathbf{R}$. Later on, we will argue that the string duality then implies that M2 brane probes of X_4 are dual to D2 brane probes of the IIA geometry, in the strong coupling limit of the later.

2.1. Geometric considerations

A convenient way to describe the Calabi-Yau geometry [26] is as a moduli space of a linear sigma model. To describe a d dimensional Calabi-Yau manifold X_d we start with a copy of $\mathbf{C}^{N+d}$, for some N , parameterized by complex coordinates

$$\phi_i, \quad i = 1, \dots, N + d,$$

Next, for each ϕ_i , we pick a set of charges Q_a^i , for $a = 1, \dots, N$ satisfying

$$\sum_i Q_i^a = 0. \quad (2.1)$$

The Calabi-Yau manifold is then obtained by setting

$$\sum_i Q_i^a |\phi_i|^2 = r^a, \quad (2.2)$$

and dividing by the gauge group

$$\phi_i \rightarrow \phi_i \exp(i \lambda_a Q_a^i). \quad (2.3)$$

The parameters r^a correspond to Kahler moduli of the Calabi-Yau manifold. Mathematically, the above construction is called a symplectic quotient. As explained in [26], symplectic quotient construction can be realized physically as a Higgs branch of a (2, 2) supersymmetric linear sigma model in two dimensions, with ϕ_i corresponding to the bottom components of chiral fields Φ_i , and with gauge group $U(1)^N$. Closer to our purposes, it can also be interpreted in terms of a theory in one dimension higher, i.e. in terms of a Higgs branch of an abelian gauge theory in three dimensions, with four supercharges.

We will now show that we can view the d dimensional Calabi-Yau threefold X_d as an S^1 fibration over a base, which itself is a fibration of a $d - 1$ dimensional Calabi-Yau X_{d-1} over a line $\mathbf{R}$. To see this, consider adding a complex variable

$$r_0 + i \theta_0$$

and pick a set of charges Q_i^0 , which also satisfy the Calabi-Yau condition,

$$\sum_i Q_i^0 = 0.$$

To avoid changing the manifold, we introduce an additional constraint

$$\sum_i Q_i^0 |\phi_i| = r_0 \tag{2.4}$$

(note that r_0 is variable now) and an additional gauge symmetry

$$\begin{aligned} \theta_0 &\rightarrow \theta_0 + \lambda \\ \phi_i &\rightarrow \exp(i Q_i^0 \lambda) \phi_i. \end{aligned} \tag{2.5}$$

Namely, using (2.4) we can solve for r_0 and gauge away θ_0 using (2.5). So, as expected, we have just written the original Calabi-Yau X_d in a different way⁷.

However, this gives us a way to think about X_d as a circle fibration. Namely, the S^1 fiber of the Calabi-Yau is θ_0 . To find the base, we consider a projection that "forgets" θ_0 . At *fixed* r_0 , the base is simply a $d - 1$ dimensional Calabi-Yau manifold X_{d-1} , given by solving (2.2)(2.4)

$$\begin{aligned} \sum_i Q_i^a |\phi_i|^2 &= r^a, \\ \sum_i Q_i^0 |\phi_i| &= r^0 \end{aligned} \tag{2.6}$$

and dividing by $N + 1$ $U(1)$ gauge transformations (2.3) and (2.5). Allowing r_0 to vary, the lower dimensional Calabi-Yau manifold X_{d-1} is a fibration over the real line parameterized by r_0 , where as we vary r_0 , the Kahler moduli of X_{d-1} vary according to (2.6).

⁷ We could also consider replacing r_0 by kr_0 while giving θ_0 charge k in (2.5), corresponding to sending θ_0 to $\theta_0 + k\lambda$ instead. In this case we do change the manifold, from X_d to a $\mathbf{Z}_k$ quotient $X_d/\mathbf{Z}_k$, since gauge transformations by $\lambda = 2\pi i/k$ leave θ_0 invariant.

We can easily find the first Chern class of the fibration. To begin with, note that

$$d\theta_0$$

is not gauge invariant because $d\theta_0$ transforms under (2.5). The gauge invariant combination is

$$d\theta_0 + \sum_j i q_j d\phi_j / \phi_j$$

where

$$\sum_j q_j Q_j^0 = 1, \quad \sum_j q_j Q_j^a = 0, \quad a = 1, \dots, N$$

Then $A_{RR} = \sum_j q_j d\phi_j / \phi_j$ is the connection on the circle bundle over $X_3 \times \mathbf{R}$ whose curvature is

$$F_{RR} = dA_{RR} = \sum_j q_j \omega_j \quad (2.7)$$

where $\omega_j = \delta^2(\phi_j) d\phi_j \wedge d\bar{\phi}_j$ is a two-form with δ -function support on the divisor D_j corresponding to setting $\phi_j = 0$. We can write

$$[F_{RR}] = \sum_j q_j [D_j], \quad (2.8)$$

for the cohomology classes $[F_{RR}]$ and $[D_i]$ of F_{RR} and ω_i , respectively. Consider now the flux of F_{RR} through a compact 2-cycle C in the geometry,

$$\int_C F_{RR}.$$

There is a correspondence between generators of $H_2(X_{d-1})$ and the $U(1)$ gauge groups in the linear sigma model. For a curve C , let

$$\sum_i Q_i^C |\phi_i|^2 = r_C$$

denote the corresponding D-term. In particular, r_C is the Kahler class of the curve. It is a standard result in toric geometry (see for example [27] for a recent review) that

$$\#(D_j \cap C) = Q_j^C,$$

and using this, we can evaluate

$$\int_C F_{RR} = \sum_j q_j \#(D_j \cap C) = \sum_j q_j Q_j^C.$$

By the usual IIA/M-theory duality, it follows that M theory, compactified on circle fibered X_d , is dual to IIA on the base of the circle fibration. Moreover the curvature of the circle fibration, F_{RR} above, becomes the RR 2-form flux on $X_{d-1} \times \mathbf{R}$. In the present context, we are interested in this duality where $d = 4$, and we are relating M-theory on Calabi-Yau fourfold X_4 to type IIA on Calabi-Yau threefold X_3 , with flux, fibered over $\mathbf{R}$,

$$\text{M - theory on } X_4 \quad \Leftrightarrow \quad \text{IIA on } X_3 \times \mathbf{R}.$$

Before we go on, we must note a few subtleties. Firstly, as explained in [26], the linear sigma model describes not just the manifold, but also its moduli space. However, as explained in [28], the non-geometric phases are absent in M-theory. So, the linear sigma models that describe not only the Calabi-Yau fourfolds for M-theory compactifications, but also the moduli space of M-theory are rather special – or at least, they are not the same ones as conventionally discussed in IIA. Secondly, when describing fibrations with X_3 used as a base, we would like X_3 as well to be in a geometric phase for all values of r_0 . Otherwise, the interpretation of our construction is less obvious. This constrains the types of charges Q^0 we can consider. Thirdly, we have not excluded the possibility that, not only RR fluxes, but also their sources would be turned on on X_{d-1} . In other words, sometimes, the IIA dual would involve D6 branes⁸. There is a-priori nothing wrong with this, but for our purposes, we are interested in those cases without the explicit D6 branes. It would be nice to have a direct, geometric, classification of linear sigma models and their circle reductions, that satisfy all of these constraints.

Instead of tackling this problem head on, we will use string theory as a guide. In the next sections, we will construct the linear sigma models for X_3 as low energy effective field theories on the D2 brane probes in IIA string theory. We will explain how turning on fluxes and fibered X_3 over $\mathbf{R}$ modifies the linear sigma model. Moreover, we will show that the resulting manifolds can be viewed as a Calabi-Yau fourfold X_4 fibered over $X_3 \times \mathbf{R}$. It is well known that D-branes probe only geometric phases of the Calabi-Yau manifolds [29]. This will automatically solve the problems one and two above. Moreover, since we only consider those deformations that correspond to turning on RR fluxes through cycles on X_3 , there are no D6 branes present by construction.

⁸ A simple example of this is the simplest case of our construction. Namely, take $d = 2$ and consider $\mathbf{C}^2$, with coordinates x_1, x_2 as a fibration over $\mathbf{C} \times \mathbf{R}$ where we introduce a D-term constraint $|x_2|^2 - |x_1|^2 = r_0$, and divide by $(\theta_0, x_1, x_2) \sim (\theta_0 + \lambda, x_1 e^{i\lambda}, x_2 e^{-i\lambda})$. It is easy to see that $F_{RR} = \delta(x_1) dx_1 \wedge d\bar{x}_1$ has flux through the two sphere surrounding the origin of $\mathbf{C} \times \mathbf{R}$. In other words, there is a D6 brane sitting at the origin. This is as expected, since the quotient by θ_0 corresponds precisely to viewing $\mathbf{C}^2$ as Taub-Nut.

3. String Duality and D-branes on Local Calabi-Yau

Consider the theory on N D2 branes probing a local toric Calabi-Yau X_3 , near the place where X_3 develops a singularity. Before turning on fluxes or fibering, this turns out to be a well known quiver theory gauge in three dimensions, preserving $\mathcal{N} = 2$ supersymmetry. As explained in the introduction, the theory is the same as the theory on D3 branes probing X_3 , dimensionally reduced to three dimensions. The latter was studied in numerous places, for example [12,13,14,15]. After reviewing this, we consider turning on RR fluxes through the vanishing cycles of X_3 . We will show that these generate Chern-Simons terms for the 3d gauge theory. To preserve $\mathcal{N} = 2$ supersymmetry on the branes, than turning on fluxes has to be accompanied with fibering the Calabi-Yau threefold X_3 over the one spatial direction transverse to the branes. This corresponds to turning on $\mathcal{N} = 2$ Chern-Simons terms on the D2-branes. These are precisely the three-fold fibrations that we showed are dual to M-theory on Calabi-Yau fourfolds X_4 ! In particular, IIA/M-theory duality implies that, at strong coupling the D2 brane gauge theory goes over to theory on N M2 branes probing X_4 . Moreover, at strong coupling the kinetic terms on the gauge fields vanish, so the natural description of this is a quiver Chern-Simons theory with $\mathcal{N} = 2$ supersymmetry.

As a further test, the IIA/M-theory duality implies that the center of mass $U(1)$ gauge field on one D2 brane probing X_3 is dual to a compact scalar describing the position of the M2 brane on the M-theory circle. For $N = 1$, we can explicitly dualize the center of mass $U(1)$ field on the D2 brane probe of our geometry, and show that the result is a linear sigma model on X_4 , as expected. Moreover, we can show that the circle is fibered over X_3 in a manner consistent with the RR fluxes turned on, thus closing the loop of correspondences.

3.1. D2 brane gauge theory on X_3

Before turning on fluxes, or fibering, the local Calabi-Yau manifold X_3 preserves 8 supercharges. The N D2 branes probing this break half of the supersymmetries, preserving four supercharges, or $\mathcal{N} = 2$ supersymmetry in three dimensions. The theory on the brane probe is a $\mathcal{N} = 2$ quiver gauge theory with superpotential. The data of the theory can be decoded from the internal geometry. In particular this means that, at the classical level, the quiver for N D2 brane probes is the same as the quiver for N D0 branes or N D3 branes probing the same geometry – it is only the dimension of the D-branes that changes. The fact that the kinematics of the theories is the same, is a consequence of T-duality

in the non-compact dimensions. This fact was also used recently in [30], in a different context.

When X_3 is smooth, the theory on N D2 brane probes, at low enough energies, becomes the same as the theory on N D2 branes probing flat space – so it is the maximally supersymmetric $U(N)$ gauge theory in three dimensions. At a singularity, however, the D2 branes split into a collection of fractional branes, carrying charges of D6, D4 and D2 branes wrapping wrapping 4, 2 and 0 dimensional cycles shrinking at the singularity (see for example, [31][18][12]) . For each such fractional brane on a vanishing cycle Δ_α , we get a node of the quiver. If the D2 brane splits into a collection of n cycles

$$\sum_{\alpha=1}^n d_\alpha \Delta_\alpha \tag{3.1}$$

we get a

$$U(d_1 N) \times \dots \times U(d_n N)$$

quiver theory on the branes at the singularity. Moreover, there are $n_{\alpha\beta}$ arrows from the node α to node β corresponding to bifundamental fields $\Phi_{\alpha\beta}^a$,

$$\Phi_{\alpha,\beta}^a : \alpha \longrightarrow \beta,$$

in $(d_\alpha N, \overline{d_\beta N})$ representation, with $a = 1, \dots, n_{\alpha\beta}$ (see next section for examples). There is a gauge invariant superpotential

$$W(\Phi),$$

which can only depend on the complex structure moduli of X_3 . Finally, the Kahler moduli of X_3 enter the D-terms of the theory. In particular, the Fayet-Iliopoulos parameters r_α for the $U(1)$ factors of the gauge group depend on them, as

$$\sum_{\alpha=1}^n r_\alpha \text{Tr} D_\alpha.$$

Each vanishing cycle carries definite D-brane charge. We can describe the charge of branes wrapping Δ_α in terms of its homology cycles in $H_{even}(X_3)$ as

$$[\Delta_\alpha] = \sum Q_6^a [D_a] + Q_4^j [C_j] + Q_2 [pt]$$

where Q_6 denotes the D6 brane charge and D the 4-cycle class the D6 branes wrap, Q_4 the D4 brane charge, and C a 2-cycle class, and Q_2 the D2 brane charge. The charges are such that $\sum_\alpha d_\alpha \Delta_\alpha$ in (3.1) has the charge of one D2 brane, and nothing else. Note that some of the brane charges appearing must be negative, since d_α are all non-negative. At the singularity the appropriately chosen combinations of D-branes and anti D-branes can be mutually supersymmetric. This is precisely what allows the D2 brane to split into fractional branes in the first place.

3.2. D2 branes in IIA on X_3 with flux

Consider turning on RR 2-form on X_3 . We can write

$$F_{RR} = \sum_I q_I \omega_I^{(2)} \quad (3.2)$$

where q_I are integers and $\omega_I^{(2)}$ are two-forms with δ -function support on divisors D_I in X_3 (F_{RR} is given as a form here, not a class on X_3 , so the divisors D_I need not all be compact). We would like to know what effect this has in the D2 brane gauge theory at the singularity.

Consider N D4 branes wrapping a vanishing 2-cycle C in X_3 . The RR field enters the theory on the branes via a Wess-Zumino coupling

$$\int_{C \times R^{2,1}} A^{RR} \text{Tr} F \wedge F$$

Note that, even though C is a shrinking cycle, we are allowed to use the geometric description above, since the coupling is topological, and the metric does not enter. This coupling gives rise to the Chern-Simons term on the D-brane world volume. Integrating by parts, we can rewrite this as

$$\int_{C \times R^{2,1}} F^{RR} \text{Tr} \omega_{CS} = k \int_{R^{2,1}} \text{Tr} \omega_{CS}$$

where $\omega_{CS} = A \wedge dA + \frac{2}{3} A \wedge A \wedge A$ is the Chern-Simons form, and

$$k = \int_C F_{RR}$$

To compute k , we use the description of F_{RR} in terms of forms with δ function support in (3.2) to express k in terms of intersection numbers of C with divisors D_i ,

$$k = \sum_I q_I \#(D_I \cap C). \quad (3.3)$$

This fractional brane wrapped on C could also carry D2 brane charges. Since these would have entered as a first Chern class of the gauge field on the D4 brane, they cannot affect the Chern-Simons coupling above.

Similarly, if we had a D6 brane wrapping a 4-cycle D the Chern-Simons coupling would be given by

$$k = \int_D F_{RR} \wedge \text{Tr} F.$$

This reduces to (3.3), where the role of C is now played by the two-cycle class dual to $\text{Tr} F$ inside the divisor D . This is where the D4 brane charge is induced. Note that in the wrapped D6 brane case, the fluxes of RR four-form G_{RR} can contribute to the level as well, by

$$\delta k = \int_D G_{RR}.$$

We can similarly represent G_{RR} by a 4-form

$$G_{RR} = \sum_A p_A \omega_A^{(4)},$$

in terms of 4-forms $\omega_A^{(4)}$ with δ -function support on curves C_A , and then

$$\delta k = \sum_A p_A \#(C_A \cap D).$$

In summary, turning on RR fluxes corresponds to turning on Chern-Simons terms. It is easy to see from the above formulas, that the generic combination of 2- and 4-form fluxes corresponds to choosing generic Chern-Simons couplings k_α for the nodes of the quiver, subject to

$$\sum_{\alpha=1}^n k_\alpha = 0. \quad (3.4)$$

This is a consequence of the fact that the net D6 brane and D4 brane charges of the quiver sum up to zero, by construction.

Now, if we were to turn on just fluxes in the Calabi-Yau, the fluxes would break the supersymmetry on the brane to $\mathcal{N} = 1$. We will return to this case in the last section of the paper. Suppose however that we want to preserve $\mathcal{N} = 2$ supersymmetry. This is the same amount of supersymmetry preserved by an M2 brane on a Calabi-Yau fourfold. In this case, the Chern-Simons coupling induced by the flux has to be accompanied with the additional terms, corresponding to

$$k \int d^4 \theta V \Sigma(V)$$

where V is the vector multiplet, and Σ is the related linear multiplet⁹. The bosonic components of the above are

$$k \left(\text{Tr} \omega_{CS}(A) + 2 \text{Tr} D \sigma \right)$$

⁹ Σ is defined in terms of V by $\Sigma = \int_0^1 dt \bar{D}(e^{tV} D e^{-tV})$. In the abelian case, we have simply $\Sigma = \bar{D} D V$.

where σ is the real scalar field in the vector multiplet, and D is the D-term¹⁰.

We see from the above that, if we want to preserve $\mathcal{N} = 2$ supersymmetry, in the presence of RR fluxes, (some combination of) Kahler moduli of the Calabi-Yau X_3 are no longer parameters in the theory – but they become variable. More precisely, the vanishing of the potential in $2 + 1$ dimensions requires [4,5]

$$\sigma_\alpha \Phi_{\alpha\beta}^a = \Phi_{\alpha\beta}^a \sigma_\beta.$$

To see what this means, consider for simplicity, the case of a single D2 brane, $N = 1$ on X_3 . Then, on the Higgs branch, the above is solved by

$$\sigma_\alpha = r_0 \mathbf{1}_{d_\alpha}, \quad \alpha = 1, \dots, n \quad (3.5)$$

for some variable r_0 . In particular, this means that the Fayet-Iliopoulos term for the gauge group on node Δ_α is given by

$$r_\alpha = k_\alpha r_0 \quad (3.6)$$

Since σ 's parameterize the positions of the branes along the one $\mathbf{R}$ direction in $\mathbf{R}^{3,1}$ transverse to the D2 branes, this means two things: first we should identify r_0 with coordinate on $\mathbf{R}$,

$$r_0 \quad \leftrightarrow \quad \text{coordinate on } \mathbf{R}.$$

Second, it means that X_3 is fibered over $\mathbf{R}$ in a manner that correlates with the RR fluxes turned on. For N D2 branes we just get the symmetric product version of this, with $\sigma_\alpha = \sigma_\beta$ describing N branes at different positions on $\mathbf{R}$.

Now, we showed that the IIA compactification on a local Calabi-Yau threefold X_3 where we turn on RR 2-form fluxes and fiber the manifold over $\mathbf{R}$ by allowing the Kahler moduli to vary is *dual* to M-theory on Calabi-Yau fourfold X_4 . This *implies* that the gauge theory describing D2 branes on X_3 in this background, flows, in the IR to theory on M2 branes probing X_4 . It is natural to *conjecture* – based on string/M-theory duality – that the theory on N M2 branes probing X_4 is the quiver Chern-Simons theory obtained from the above by setting the gauge kinetic terms to zero, since these vanish in the IR on dimensional grounds¹¹.

¹⁰ The vector multiplet has the expansion $V = -2i\theta\bar{\theta}\sigma + 2\theta\gamma^\mu\bar{\theta} + \theta^2\bar{\theta}^2 D$.

¹¹ Note that we can also relax the condition (3.4). This corresponds to turning on RR zero form flux, which couples to the D2 brane charge. This agrees with the proposal recently in [32,33], for Chern-Simons theories dual to massive IIA backgrounds.

3.3. One D2/M2 brane

As additional evidence for the proposed duality, consider again the case of a single D2 brane in IIA. It is well known that the $U(1)$ gauge field A_0 on the D2 brane probe is dual, via the scalar-vector duality in three dimensions to the compact scalar θ_0 related to A_0 via

$$dA_0 = *d\theta_0. \quad (3.7)$$

This scalar describes the position of the M2 brane on the M-theory circle. Based on the IIA on X_3 /M theory on X_4 duality, we expect that when we turn on $\mathcal{N} = 2$ Chern-Simons terms on the branes, θ_0 should be fibered over the base $X_3 \times \mathbf{R}$ in such a way so as to give a Calabi-Yau fourfold X_4 . Moreover, the circle fibration should have the right first Chern class on X_3 to correspond to RR 2-form flux we had started with. We will see in detail that this is indeed the case in the examples we study in the next section. For now, we will just sketch how this comes about.

For most singularities, and all the singularities we will study in this paper, $d_\alpha = 1$, for all α ¹². In this case the theory is abelian, with gauge group

$$U(1)^n$$

for a quiver with n nodes.

The moduli space is the space of solutions to minima of F and D-term potentials, modulo the gauge transformations. Before turning on fluxes, the moduli space of this theory, the Higgs branch, is the Calabi-Yau manifold $X_3 \times \mathbf{R}$. As above, the $\mathbf{R}$ direction is parameterized by one massless combination of σ 's. On the Higgs branch, all components of the gauge fields with charged matter become massive. However, there is one decoupled $U(1)$ gauge field, under which nothing is charged. This corresponds to the diagonal combination

$$A_0 = \frac{1}{n} \sum_{\alpha} A_{\alpha}.$$

This component becomes the $U(1)$ gauge field on the D2-brane at a generic point in X_3 . Dualizing A_0 to the compact scalar θ_0 via (3.7), the moduli space of the M2 brane is a direct product $\mathbf{S}^1 \times X_3 \times \mathbf{R}$. Moreover, the Fayet-Iliopoulos terms in the gauge theory are identified with the Kahler moduli of X_3 , and they are independent of where in $\mathbf{R}$ we are.

¹² For examples where not all $d_\alpha = 1$ see [12].

Now consider turning on 2- and 4-form fluxes. This generates Chern-Simons terms

$$\int d^3x \sum_{\alpha=1}^n k_{\alpha} A_{\alpha} \wedge dA_{\alpha}$$

where $\sum_{\alpha} k_{\alpha} = 0$, as we explained. The effect of this on the moduli space is twofold. On the one hand, turning on fluxes modifies the Fayet-Iliopoulos terms in the vacuum corresponding to fibering the X_3 over $\mathbf{R}$ as in (3.6). The effect on the gauge transformations is as follows. Put, $A_{\alpha} = A_0 + \hat{A}_{\alpha}$, where $\sum_{\alpha} \hat{A}_{\alpha} = 0$. Then A_0 enters the Chern-Simons terms via the coupling¹³

$$\int_{\mathbf{R}^{2,1}} d^3x \sum_{\alpha} k_{\alpha} \hat{A}_{\alpha} \wedge dA_0. \quad (3.8)$$

Dualizing A_0 to the compact scalar θ_0 , replaces dA_0 by $d\theta_0$. Presence of (3.8) means that θ_0 picks up a logarithmic charge k_{α} under the gauge group on node α . In particular, while $d\theta_0$ is no longer well defined, the combination

$$d\theta_0 + i \sum_{\alpha} k_{\alpha} \hat{A}_{\alpha}$$

is well defined.

We can view this in two different ways. Firstly, this implies that the moduli space is Calabi-Yau fourfold X_4 . It is obtained by *not* dividing by the $U(1)$ gauge transformations generated by

$$\sum_{\alpha} k_{\alpha} \hat{A}_{\alpha};$$

these we can use to set θ_0 to zero¹⁴. This is related by supersymmetry to the one linear combination of D -terms we need not impose: we can use them to solve for r_0 , the superpartner of A_0 and θ_0 .

Second, this allows us to view the Calabi-Yau fourfold X_4 as a circle fibration over $X_3 \times \mathbf{R}$, with θ_0 parameterizing the fiber. We will now argue that we can think of $\sum_{\alpha} k_{\alpha} F_{\alpha}$ as the RR flux itself, or more precisely that

$$[F_{RR}] = \sum_{\alpha} k_{\alpha} [D_{\alpha}], \quad (3.9)$$

¹³ Note that the other Chern Simons terms vanish on the Higgs branch, since all the components of the gauge fields under which matter is charged are massive.

¹⁴ When the greatest common denominator of the k_{α} 's is not 1, this leaves a discrete subgroup of the gauge symmetry unbroken, this leaves over a discrete subgroup of the gauge symmetry unbroken. The moduli space is then an orbifold by this symmetry.

where D_α is the divisor class in X_3 corresponding to the $U(1)$ on the node α ¹⁵. To see this [23] recall first of all that on the D2 brane there is a Wess-Zumino coupling

$$\int_{\mathbf{R}^{2,1}} d^3x F_{RR} \wedge A_0.$$

In the presence of the above flux, the action of a D2 brane wrapped on a curve C would get shifted by $\sum_\alpha \#(k_\alpha D_\alpha \cap C)$ times $\int A_0$.

This is exactly what (3.8) implies. Namely, configurations of D2 brane wrapped on a curve C in the linear sigma model carries non-zero vortex charge [26]. In particular, a D2 brane wrapped on C carries vortex charge

$$\int F_\alpha = \#(D_\alpha \cap C)$$

for the $U(1)$ on node α . Correspondingly, in the presence of the coupling (3.8) the action of a D2 brane wrapped on C gets modified precisely by the same amount, as it does in the presence of the RR flux (3.9), as we claimed. In the next section, we will work this out explicitly in some examples.

Before we go on, note that the $N = 1$ case gives a physical realization to the linear sigma models in the previous section¹⁶. We will see this in the examples in following sections. More precisely, as noted in [29], D-branes tend to see only the geometric phases of the theory. This is just what is needed for our purposes. Namely, as argued in [34], the non-geometric phases are absent in M-theory as well.

In the next sections we present some examples of the theories we discussed above. All of the examples below have appeared in the literature, we are just giving them a new interpretation, in terms of the IIA/M-theory duality.

¹⁵ D_α corresponds to setting to zero a product of linear sigma model variables with coupling with charge 1 to $\hat{A}_\alpha$, and charge zero to the rest.

¹⁶ A-priori, the linear sigma model in question differs from the ones in section 2 by the presence of superpotentials. This is a technicality. In fact, as we'll see in the next section, the solutions to F -term equations can be often rewritten as minima of an *effective* linear sigma model without superpotential, [29]. This fact was used extensively in [19]. In such cases the theories on the D-branes are called toric. There are also non-toric examples, related to the toric ones by Seiberg dualities.

4. Example 1: Conifold and the ABJM theory

The Calabi-Yau X_3 is the total space of $O(-1) \oplus O(-1)$ bundle over $\mathbf{P}^1$. The $\mathbf{P}^1$ corresponds to the one shrinking 2-cycle of this geometry. There are two fractional branes,

$$\Delta_1, \quad \Delta_2,$$

whose D-brane charges are given by

$$[\Delta_1] = [pt] - [\mathbf{P}^1], \quad [\Delta_2] = [\mathbf{P}^1]. \quad (4.1)$$

In other words, Δ_2 corresponds to a D4 brane wrapping the $\mathbf{P}^1$, and Δ_1 to the anti-D4 brane bound to one unit of $D2$ brane. The latter can be thought of as turning on $\int_{\mathbf{P}^1} F = -1$ on the anti-D4 brane. Thus, one D2 brane probing X_3 corresponds to

$$[\Delta_1] + [\Delta_2].$$

The quiver is given by $U(N) \times U(N)$, $\mathcal{N} = 2$ gauge theory in 3 dimensions, with two pairs of bifundamentals $A_{1,2}$ in $(N, \bar{N})$, and anti-bifundamentals $B_{1,2}$ in $(\bar{N}, N)$, and superpotential

$$W = \lambda (Tr A_1 B_1 A_2 B_2 - Tr A_1 B_2 A_2 B_1).$$

The Higgs branch of the theory describes N D2 branes probing $X_3 \times \mathbf{R}$. Namely, for $N = 1$, the superpotential vanishes. The potential for the $\sigma_{1,2}$ vanishes by setting

$$\sigma_1 = \sigma_2 = r_0, \quad (4.2)$$

where we view r_0 as a coordinate on $\mathbf{R}$ inside $\mathbf{R}^{3,1}$. The D-term potential vanishes for

$$|A_1|^2 + |A_2|^2 - |B_1|^2 - |B_2|^2 = r_1, \quad (4.3)$$

where r_1 is the Fayet-Iliopoulos term for the first $U(1)$. For the second $U(1)$ the charges are opposite, and $r_2 = -r_1$. Dividing by the gauge group, the moduli space is the conifold, X_3 times $\mathbf{R}$. While the off-diagonal gauge fields are Higgsed, the diagonal $U(1)$ survives, since nothing is charged under it. It is identified with the center of mass $U(1)$ gauge field on the D2 brane at a generic point in the moduli space. For general N , the Higgs branch is the symmetric product $Sym^N(X_3 \times \mathbf{R})$ describing N identical D2 branes moving about on $X_3 \times \mathbf{R}$.

Consider now deforming the theory by $\mathcal{N} = 2$ Chern-Simons terms for the two gauge groups,

$$k \int d^4\theta \left(\text{Tr } V_1 \Sigma(V_1) - \text{Tr } V_2 \Sigma(V_2) \right) \quad (4.4)$$

where $V_{1,2}$ are the vector multiplets corresponding to the two nodes. This is precisely the theory studied in [3]¹⁷. Turning on $\mathcal{N} = 2$ Chern-Simons terms in the D-brane theory means that we are deforming the bulk IIA theory by turning on RR 2-form flux in through the $\mathbf{P}^1$, and fibering X_3 over $\mathbf{R}$. To see this, consider again the moduli space of the theory for $N = 1$. In this case, the Chern-Simons interaction makes Fayet-Iliopoulos parameters dynamical, with

$$r_1 = k r_0 = -r_2$$

where r_0 is the vev of the σ fields in (4.2). We still have to divide by the gauge group. Dualizing the center of mass gauge field to a compact scalar θ_0 , the latter picks up a logarithmic charge k under the off diagonal $U(1)$. Thus the gauge symmetry acts as

$$\begin{aligned} \theta_0 &\rightarrow \theta_0 + k\lambda \\ A_{1,2} &\rightarrow A_{1,2} e^{i\lambda} \\ B_{1,2} &\rightarrow B_{1,2} e^{-i\lambda} \end{aligned} \quad (4.5)$$

Solving the D-term constraint for r_0 , and using (4.5) to set θ_0 to zero, the moduli space is a copy of $\mathbf{C}^4$, parameterized by $A_{1,2}$, and $B_{1,2}$. We still have to divide by the discrete gauge transformations that leave θ_0 invariant, corresponding to $\lambda = 2\pi/k$. Correspondingly, the moduli space is the fourfold

$$X_4 = \mathbf{C}^4 / \mathbf{Z}_k,$$

as explained in [3]. On the other hand, this allows us to view X_4 as an S^1 fibration over $X_3 \times \mathbf{R}$. Namely, projecting to the the base, by forgetting θ_0 , and fixing a point r_0 in $\mathbf{R}$, we get a copy of X_3 . Now consider the first Chern class of the fibration. While $d\theta_0$ itself is not well defined, for example

$$d\theta_0 + ik dB_1/B_1$$

is well defined over $X_3 \times \mathbf{R}$. Hence, we can identify

$$A_{RR} = k dB_1/B_1.$$

¹⁷ More precisely, it is the same theory provided we tune $\lambda = 1/k$, when the theory has an enhanced supersymmetry.

The corresponding curvature $F_{RR} = dA_{RR}$ is

$$F_{RR} = k \omega_{B_1}$$

with $\omega_{B_1} = i\delta^2(B_1) dB_1 \wedge d\bar{B}_1$. The cohomology class of F_{RR} is the same as k copies of divisor D_{B_1} corresponding to setting $B_1 = 0$,

$$[F_{RR}] = k[D_{B_1}]. \quad (4.6)$$

As we explained in the previous section, the RR fluxes turn on Chern-Simons terms on the brane. Given the D-brane charges (4.1), we have

$$k_2 = \int_{\mathbf{P}^1} F_{RR} = -k_1$$

Consistency requires that the Chern-Simons terms induced by the flux agree with (4.4).

As we explained, given (4.6) we have

$$\int_{\mathbf{P}^1} F_{RR} = k \#(D_{B_1} \cap \mathbf{P}^1).$$

We can read off the intersection number from (4.3). Namely, (4.3) is the D-term constraint corresponding to the class of the $\mathbf{P}^1$, so the intersection of the divisor D_{B_1} with the $\mathbf{P}^1$ is just the charge of B_1 under the corresponding $U(1)$. This is -1 , so

$$\#(D_{B_1} \cap \mathbf{P}^1) = -1,$$

giving $k_1 = k = -k_2$, as we had expected.

5. Example 2: $\mathbf{C}^2/\mathbf{Z}_2 \times \mathbf{C}$ singularity

The Calabi-Yau

$$X_3 = \mathbf{C}^2/\mathbf{Z}_2 \times \mathbf{C}$$

is an orbifold, whose resolution is an $O(-2) \oplus O$ bundle over a $\mathbf{P}^1$. Correspondingly, there is one vanishing two-cycle, the $\mathbf{P}^1$ in the base. The theory on the D-branes on X_3 was discovered in [24]. There are two fractional branes,

$$\Delta_1, \quad \Delta_2,$$

with

$$[\Delta_1] = [pt] - [\mathbf{P}^1] \quad [\Delta_2] = [\mathbf{P}^1].$$

The quiver is given by $U(N) \times U(N)$ gauge theory with a pair of bifundamental chiral multiplets A_1, B_1 in $(N, \bar{N})$, anti-bifundamentals A_2, B_2 , in $(\bar{N}, N)$ and an additional pair of adjoints $\Phi_{1,2}$ of the two groups. The superpotential¹⁸ is

$$W = \text{Tr} \Phi_1 (A_1 A_2 - B_1 B_2) - \text{Tr} \Phi_2 (A_2 A_1 - B_2 B_1).$$

This theory was studied in the present context in [5]. For a single D2 brane on X_3 , the moduli space is $X_3 \times \mathbf{R}$. The $\mathbf{R}$ direction is parameterized by $\sigma_1 = r_0 = \sigma_2$, as before. X_3 emerges by setting the F - and the D -terms to zero and dividing by the gauge group. Setting the F-terms to zero we have $\Phi_1 = \Phi_2$, which parameterize a copy of $\mathbf{C}$. In addition, we have

$$A_1 A_2 = B_1 B_2. \tag{5.1}$$

The D-term for the first $U(1)$ gives

$$|A_1|^2 + |B_1|^2 - |A_2|^2 - |B_2|^2 = r_1,$$

and similarly for the second $U(1)$ with $r_1 = -r_2$, and signs of all the charges reversed. It is useful to rewrite the F-term constraints as D-term constraints, so that we get a linear sigma model without superpotential. We can solve (5.1) introducing four new variables, and putting

$$A_1 = x_1 x_0, \quad A_2 = x_2 x_3, \quad B_1 = x_1 x_0, \quad B_2 = x_2 x_3.$$

There is a redundancy inherent in this, which we can remove by simultaneously introducing a *new* $U(1)$ gauge field $U(1)_{aux}$ under which A 's and B 's are neutral, and $x_{1,2}$ have charge $+1$, and $x_{0,3}$ charge -1 . This introduces a new D-term constraint

$$|x_1|^2 + |x_2|^2 - |x_0|^2 - |x_3|^2 = 0. \tag{5.2}$$

¹⁸ In fact the conifold theory in the previous subsection above was obtained as a deformation of the orbifold theory. In the gauge theory, the deformation corresponds to adding a mass term $\frac{m}{2}(\text{Tr} \Phi_1^2 - \text{Tr} \Phi_2^2)$, with $m = 1/\lambda$.

The FI term for this auxiliary $U(1)$ has to be set to zero for this to be equivalent to the solutions of F-term equations. The fields x_i also carry charges under the original gauge fields, since the A 's and the B 's did. The original D-terms translate to

$$|x_3|^2 - |x_0|^2 = r_1. \quad (5.3)$$

For $r_1 \geq 0$, we can use (5.3) and the corresponding gauge symmetry to solve for x_3 , so the moduli space is simply

$$|x_1|^2 + |x_2|^2 - 2|x_0|^2 = r_1. \quad (5.4)$$

modulo $U(1)$. This, is a copy of (the resolution of) $\mathbf{C}^2/Z_2$, and together with a copy of $\mathbf{C}$ parameterized by the adjoints, it gives X_3 .

As an aside, note that the orbifold phase is absent. This would have corresponded to taking $r_1 < 0$. However, we are not allowed to do that, since we can no longer solve (5.3) in the manner we did before. Instead, what we need to do is exchange the roles of x_0 and x_3 , and then we recover a geometric phase again. As we discussed before, this is just what is needed for compactification of M-theory, since there the non-geometric phases have to be absent [26].

Consider now turning on $\mathcal{N} = 2$ Chern-Simons couplings for the two gauge groups of the quiver

$$k \int d^4\theta \left(\text{Tr } V_1 \Sigma(V_1) - \text{Tr } V_2 \Sigma(V_2) \right)$$

The flux has two effects. The FI parameter of (5.4) becomes dynamical,

$$r_1 = k r_0 = -r_2$$

and, dualizing the center of mass gauge field $A_0 = \frac{1}{2}(A_1 + A_2)$ to a dual scalar θ_0 , the corresponding gauge transformation becomes

$$\theta_0 \rightarrow \theta_0 + k\lambda, \quad x_3 \rightarrow x_3 e^{i\lambda}, \quad x_0 \rightarrow x_0 e^{-i\lambda} x_0$$

with $x_{1,2}$ invariant. This allows us to solve for r_0, θ_0 and drop these equations. Their only remnant is a discrete gauge symmetry that takes

$$x_3, x_0 \rightarrow e^{2\pi i/k} x_3, e^{-2\pi i/k} x_0$$

The D-term and gauge symmetry corresponding to the auxiliary $U(1)_{aux}$ in (5.2) are unaffected. The moduli space is a Calabi-Yau fourfold X_4 which is $\mathbf{Z}_k$ orbifold of the conifold times a copy of $\mathbf{C}$ [5,7].

Now, let us view X_4 as an S^1 fibration over $X_3 \times \mathbf{R}$. We will show that the first Chern class of the fibration is just what is needed for the RR flux to be the origin of the Chern-Simons terms. Namely, it is easy to see that

$$d\theta_0 + ik(dx_2/x_2 + dx_0/x_0)$$

is invariant under the $U(1)^2 \times U(1)_{aux}$ gauge group. Thus, compactifying M-theory on X_4 and interpreting θ_0 as the M-theory circle, we get IIA on $\mathbf{X}_3 \times \mathbf{R}$ with RR flux turned on corresponding to

$$[F_{RR}] = k[D_2] + k[D_0]$$

where D_i is a divisor corresponding to setting $x_i = 0$. Now, the Chern-Simons level should be given by

$$k_2 = -k_1 = \int_{\mathbf{P}^1} F_{RR}.$$

We have

$$\int_{\mathbf{P}^1} F_{RR} = k \#((D_2 + D_0) \cap \mathbf{P}^1)$$

and we would like to compute what this is on X_3 . Since the D-term constraint corresponding to the class of the $\mathbf{P}^1$ is (5.4) the intersection numbers are simply the charges of x_2 , x_0 under it. This gives

$$\#(D_2 \cap \mathbf{P}^1) = 1, \quad \#(D_0 \cap \mathbf{P}^1) = -2$$

we see that we recover

$$k_1 = k = -k_2,$$

as expected.

6. Example 3: The Suspended Pinch Point

In this case, the X_3 geometry has two vanishing $\mathbf{P}^1$'s, $\mathbf{P}_1^1$ with normal bundle $O \oplus O(-2)$ bundle, and $\mathbf{P}_2^1$ with normal bundle $O(-1) \oplus O(-1)$. There are now three fractional branes.

$$[\Delta_1] = [\mathbf{P}_1^1], \quad [\Delta_2] = [\mathbf{P}_2^1], \quad [\Delta_3] = -[\mathbf{P}_1^1] - [\mathbf{P}_2^1] + [\text{pt}] \quad (6.1)$$

For N D2 branes probing X_3 we get a

$$U(N) \times U(N) \times U(N)$$

quiver theory with bifundamental matter as in the figure 1. Since the brane in class Δ_1 is free to move in the O direction, (the normal bundle has one holomorphic section) there is one adjoint chiral multiplet Φ corresponding to that. The superpotential is

$$W = \text{Tr} \Phi (A_1 A_2 - C_1 C_2) + \text{Tr} B_1 B_2 C_2 C_1 - \text{Tr} B_2 B_1 A_2 A_1.$$

Fig. 1. Quiver corresponding to the N D2 branes on the Suspended Pinch Point singularity.

Consider the moduli space for one D2 brane on X_3 . As usually, there is one direction $\mathbf{R}$ parameterized by $\sigma_\alpha = r_0$, for all α . The F-term equations set

$$A_1 A_2 = C_1 C_2, \quad \Phi = B_1 B_2$$

We can write these as D-term equations by putting

$$A_1 = a_1 b_1, \quad A_2 = a_2 b_2, \quad C_1 = a_1 b_2, \quad C_2 = a_2 b_1,$$

and introducing an additional $U(1)_{aux}$ gauge symmetry, under which $a_{1,2}$ have charge $+1$ and $b_{1,2}$ have charge -1 . All in all, we have $U(1)^4$ gauge invariance, and four D-term equations

$$\begin{aligned} |a_1|^2 - |a_2|^2 &= r_1 \\ |a_2|^2 - |b_1|^2 - |B_1|^2 + |B_2|^2 &= r_2 \\ |a_2|^2 - |b_2|^2 + |B_1|^2 - |B_2|^2 &= r_3 \\ -|a_1|^2 - |a_2|^2 + |b_1|^2 + |b_2|^2 &= 0 \end{aligned} \tag{6.2}$$

where $r_1 + r_2 + r_3 = 0$. It is easy to show, solving the D-term equations and dividing by the gauge group, that the moduli space is precisely X_3 with r_1 corresponding to the size of

$\mathbf{P}_1^1$ and r_2 to $\mathbf{P}_2^1$. Namely, using the first equation, and the corresponding gauge symmetry to solve for a_1 , the moduli space can be written simply as

$$\begin{aligned} |b_1|^2 + |b_2|^2 - |a_2|^2 &= r_1 \\ |a_2|^2 - |b_1|^2 - |B_1|^2 + |B_2|^2 &= r_2 \end{aligned} \tag{6.3}$$

where the first equation now corresponds to the cohomology class of the $\mathbf{P}_1^1$ and the second to $\mathbf{P}_1^1$.

Consider now turning on $\mathcal{N} = 2$ Chern-Simons couplings. Given the D-brane charges (6.1) the Chern-Simons couplings should be related to fluxes as

$$k_1 = \int_{\mathbf{P}_1^1} F_{RR}, \quad k_2 = \int_{\mathbf{P}_2^1} F_{RR}, \quad k_3 = - \int_{\mathbf{P}_1^1} F_{RR} - \int_{\mathbf{P}_2^1} F_{RR}.$$

6.1. Case $(k_1, k_2, k_3) = (k, -k, 0)$

The Fayet-Iliopoulos terms r_1, r_2 vary over $\mathbf{R}$ parameterized by r_0 as

$$r_1 \sim r_0, \quad r_2 \sim -r_0,$$

while r_3 is a constant. We can view X_4 obtained by just dropping the first two equations in (6.2) and the corresponding $U(1)$'s, and dividing by a Z_k action that sends a_1, a_2 to $e^{2\pi i/k} a_1, e^{-2\pi i/k} a_2$. The moduli space is the $\mathbf{Z}_k$ quotient of the fourfold D_3 given in [5,7].

On the other hand, we can view X_4 as a circle fibration over $X_3 \times \mathbf{R}$ by dualizing the center of mass $U(1)$ to a compact scalar field θ_0 . Then, θ_0 is invariant under the third and fourth $U(1)$ in (6.2), and transforms under the first two with logarithmic charge k , and $-k$, respectively. We can pick, for example

$$d\theta_0 - k(da_1/a_1 + db_1/b_1)$$

as the invariant one form on $X_3 \times \mathbf{R}$. This implies

$$[F_{RR}] = k[D_{a_1} + D_{b_1}]$$

where D_{a_1}, D_{b_1} are the divisors corresponding to setting a_1 , and b_1 to zero. From (6.2), and the charges of a_1, b_1 we can read off that

$$\#(D_{a_1} \cap \mathbf{P}_1^1) = 0, \quad \#(D_{a_1} \cap \mathbf{P}_2^1) = 0, \quad \#(D_{b_1} \cap \mathbf{P}_1^1) = 1, \quad \#(D_{b_1} \cap \mathbf{P}_2^1) = -1$$

so that

$$\int_{\mathbf{P}_1^1} F_{RR} = k = - \int_{\mathbf{P}_2^1} F_{RR},$$

as expected.

6.2. The General Case $(k_1, k_2, k_3) = (k, m, -k - m)$

The Fayet-Iliopoulos terms r_1, r_3 vary over $\mathbf{R}$ parameterized by r_0 as

$$r_1 \sim mr_0, \quad r_2 \sim kr_0 \quad r_3 \sim -(k + m)r_0,$$

while r_2 is a constant. We can view X_4 obtained by dropping the first three equations and replacing them by one linear combination of them which is independent of r_0 , say k times the first equation minus m times the second. In addition, we divide by the corresponding $U(1)$ gauge symmetry. The result is a Calabi-Yau fourfold X_4 .

Now, let's view X_4 as a circle fibration over $X_3 \times \mathbf{R}$. We want to show that the corresponding circle fibration has the correct Chern class. The compact scalar θ_0 transforms with logarithmic charges k, m and $-k - m$ under the first three $U(1)$'s in (6.2) and not at all under the last one. The invariant one form is

$$d\theta_0 - (k da_1/a_1 - m db_1/b_1 + (k + m) db_2/b_2)$$

From this it follows that

$$[F_{RR}] = k[D_{a_1}] - m[D_{b_1}] + (k + m)[D_{b_2}].$$

We know the intersection numbers of D_{a_1, b_1} already. We have in addition

$$\#(D_{b_2} \cap \mathbf{P}_1^1) = 1, \quad \#(D_{b_2} \cap \mathbf{P}_2^1) = 0$$

Adding this all up, we find so that

$$\int_{\mathbf{P}_1^1} F_{RR} = k, \quad \int_{\mathbf{P}_2^1} F_{RR} = m,$$

as expected, given the D-brane charges (6.1).

7. Example 4: $\mathbf{C}^3/\mathbf{Z}_3$

In this case, the resolution of the singularity is $O(-3) \rightarrow \mathbf{P}^2$, so there is both a shrinking four cycle, the $\mathbf{P}^2$ and a shrinking 2-cycle, the $\mathbf{P}^1$ inside the $\mathbf{P}^2$. There are three vanishing cycles $\Delta_{1,2,3}$. The D-brane charges of vanishing cycles are [12]

$$\Delta_1 = -2[\mathbf{P}^2] + [\mathbf{P}^1] - \frac{1}{2}[\text{pt}], \quad \Delta_2 = [\mathbf{P}^2] \quad \Delta_3 = [\mathbf{P}^2] - [\mathbf{P}^1] - \frac{1}{2}[\text{pt}],$$

The gauge group on N D2 branes is

$$U(N) \times U(N) \times U(N),$$

with nine chiral multiplets connecting them, as in the figure 2.

Fig. 2. Quiver corresponding to the N D2 branes on $\mathbf{C}^3/\mathbf{Z}_3$. There are three bifundamentals connecting each pair nodes.

In addition, there is a superpotential

$$W = \sum_{i,j,k} \epsilon_{ijk} \text{Tr} A_i B_j C_k$$

Consider now the moduli space for a single D2 brane probe. This problem was solved explicitly in [29]. As in the previous examples, we can redefine variables to be able to rewrite the F-term equations as D-term equations. This example was worked out in detail in [29]. At the end of the day, we have an effective linear sigma model with six fields p_i , $i = 0, 1, \dots, 5$, and $U(1)^4$ gauge symmetry

$$\begin{aligned} |p_1|^2 + |p_2|^2 + |p_3|^2 - |p_0|^2 - |p_4|^2 - |p_5|^2 &= 0 \\ -|p_4|^2 + |p_5|^2 &= r_1 \\ |p_0|^2 - |p_5|^2 &= r_2 \\ -|p_0|^2 + |p_4|^2 &= r_3 \end{aligned} \tag{7.1}$$

where r_i is the FI parameter of the i 'th node, and $r_1 + r_2 + r_3 = 0$. For any choice of FI parameters, the moduli space is always $X_3 = O(-3) \rightarrow \mathbf{P}^2$, i.e. the orbifold phase is

absent. For example, for $r_2 < 0 < r_3$, we can use the last two equations above to "solve" for $p_{4,5}$ in terms of p_0 , and the moduli space is simply the solutions to

$$|p_1|^2 + |p_2|^2 + |p_3|^2 - 3|p_0|^2 = r_3 - r_2$$

which is X_3 with Kahler class $r_3 - r_2$.

Consider now turning on Chern-Simons couplings for the branes on the three nodes with

$$(k_1, k_2, k_3) = (k, -k - m, m).$$

It is easy to work out what the corresponding Calabi-Yau fourfold X_4 is. This corresponds to letting the FI parameters vary as

$$r_1 \propto k r_0, \quad r_2 \propto -(m + k) r_0, \quad r_3 \propto m r_0,$$

moreover, the compact scalar θ_0 has charges $k, -(k + m)$ and $-m$ under the three $U(1)$'s corresponding to the three nodes of the quiver, and is neutral under the auxiliary $U(1)$ (corresponding to first equation in (7.1)). The invariant one form can be written as

$$d\theta_0 + i(m dp_0/p_0 - k dp_5/p_5 + (m - k)dp_1/p_1)$$

This implies

$$[F_{RR}] = -m[D_0] - (m - k)[D_1] + k[D_5]$$

From above, we can read off,

$$\#(D_0 \cap \mathbf{P}^1) = -3, \quad \#(D_1 \cap \mathbf{P}^1) = 1, \quad \#(D_5 \cap \mathbf{P}^1) = 0$$

so

$$\int_{\mathbf{P}^1} F_{RR} = 2m + k$$

Now, consider the contribution of this flux to the Chern-Simons levels. For the three fractional branes $\Delta_1, \Delta_2, \Delta_3$, the RR 2-form flux gives:

$$(k_1, k_2, k_3) = \left(\int_{\mathbf{P}^1} F_{RR}, 0, - \int_{\mathbf{P}^1} F_{RR} \right) = (2m + k, 0, -2m - k).$$

Now, recall that we are also free to turn on RR four-form flux on the $\mathbf{P}^2$ in IIA. From the charges of the wrapped D-branes, we see that this could shift the levels by

$$(\delta k_1, \delta k_2, \delta k_3) = \left(-2 \int_{\mathbf{P}^2} G_{RR}, \int_{\mathbf{P}^2} G_{RR}, \int_{\mathbf{P}^2} G_{RR} \right),$$

which is exactly what we need, provided

$$\int_{\mathbf{P}^2} G_{RR} = m.$$

Note that, for $r_0 < 0$, we get a different assignment of fluxes. As we pass through the singularity at r_0 , and continue on to negative r_0 , the fractional branes are permuted by the quantum $\mathbf{Z}_3$ symmetry, that takes Δ_i to Δ_{i-1} [35]. This also acts on the homology in the corresponding way, namely, $([\mathbf{P}^2], [\mathbf{P}^1])$ go to $([\mathbf{P}^2] - [\mathbf{P}^1], 3[\mathbf{P}^2] - 2[\mathbf{P}^1])$, so the Chern-Simons couplings get permuted as well. For this reason, it does not follow that the four-form flux on X_3 lifts to G -flux on the fourfold.

7.1. Case $(k_1, k_2, k_3) = (0, -m, m)$

For example, consider the case where $k = 0$. Note that this does not mean that the RR 2-form flux is turned off entirely on X_3 , but just that the its cohomology class vanishes.

In this case, the Calabi-Yau fourfold X_4 is an $\mathbf{Z}_m$ quotient of an $O(-2) \oplus O(-1)$ bundle over $\mathbf{P}^2$. Namely, we can use the last equation and the corresponding gauge symmetry (7.1) to "solve" for r_0 , and θ_0 . The two left-over, independent D-term constraints are the first two. We can solve the latter one for p_5 , and the manifold becomes

$$|p_1|^2 + |p_2|^2 + |p_3|^2 - |p_0|^2 - 2|p_4|^2 = r_1$$

modulo the corresponding $U(1)$. This is the $O(-1) \oplus O(-2)$ bundle over $\mathbf{P}^2$. This agrees with [5,7]. More precisely, X_4 is a quotient of this

$$p_0, p_4 \rightarrow e^{2\pi i/m} p_0, e^{-2\pi i/m} p_4$$

which is a discrete gauge symmetry left over from solving for θ_0 . Finally, we claim that the quiver gauge theory in this case describes M2 branes on X_4 , with m units of G -flux turned on through the $\mathbf{P}^2$. At large N , the theory should be dual to M-theory on $AdS_4 \times Y^{m,2m}(\mathbf{P}^2)$ [4,22].

8. Example 5: Local F_0 and the cone over $Q^{1,1,1}$

This case is interesting, since as we will see, it will provide a new Chern-Simons theory that should be dual to N M2 branes probing a cone over $Q^{1,1,1}$. The latter is a very old example of an Einstein-Sasaki manifold. The conformal field theory dual to $AdS_4 \times Q^{1,1,1}$ has been sought for a long time. Here we will provide a string theory derivation of the dual CFT. Other proposals have been made in [9] and studied in [20] recently.

The geometry of the Calabi-Yau threefold X_3 is a line bundle over

$$F_0 = \mathbf{P}^1 \times \mathbf{P}^1.$$

In this case there are four vanishing cycles. There are two different assignments of charges we can make where the superpotential is still toric (in the sense of the footnote 14). We will pick one of these, for simplicity. The D-brane charges are [12]

$$\Delta_1 = [F_0] - [\mathbf{P}_1^1] - [\mathbf{P}_2^1] + [\text{pt}]$$

$$\Delta_2 = [F_0] - [\mathbf{P}_1^1]$$

$$\Delta_3 = -[F_0] + 2[\mathbf{P}_1^1]$$

$$\Delta_4 = -[F_0] + [\mathbf{P}_2^1]$$

Fig. 3. Quiver corresponding to the N D2 branes on local F_0 . There are two bifundamentals connecting each pair nodes.

The theory on N D2 branes is a

$$U(N) \times U(N) \times U(N) \times U(N)$$

quiver theory corresponding to the figure 3, with superpotential

$$W = \epsilon^{ik} \epsilon^{jl} \text{Tr} A_i B_j C_k D_l. \quad (8.1)$$

Consider the moduli space for $N = 1$. Before turning on superpotential, the moduli space is $\mathbf{R} \times S^1$, parameterized by $\sigma_\alpha = r_0$ and θ_0 , times X_3 . The latter is a space of solutions to F-term equations

$$A_1 C_2 = A_2 C_1, \quad B_1 D_2 = B_2 D_1$$

and D-term constraints modulo $U(1)^4$. We can rewrite the F-term constraints as D-term constraints of an auxiliary linear sigma model, by introducing 8 new variables

$$x, y, z, w, \tilde{x}, \tilde{y}, \tilde{z}, \tilde{w}$$

such that

$$\begin{aligned} A_1 &= xy, & A_2 &= xw, & C_1 &= zy, & C_2 &= zw \\ B_1 &= \tilde{x}\tilde{y}, & B_2 &= \tilde{x}\tilde{w}, & D_1 &= \tilde{z}\tilde{y}, & D_2 &= \tilde{z}\tilde{w} \end{aligned} \tag{8.2}$$

The D-term constraints now become

$$\begin{aligned} |x|^2 - |\tilde{z}|^2 &= r_1 \\ |\tilde{x}|^2 - |x|^2 &= r_2 \\ |z|^2 - |\tilde{x}|^2 &= r_3 \\ |\tilde{z}|^2 - |z|^2 &= r_4 \\ |x|^2 + |z|^2 - |y|^2 - |w|^2 &= 0 \\ |\tilde{x}|^2 + |\tilde{z}|^2 - |\tilde{y}|^2 - |\tilde{w}|^2 &= 0 \end{aligned} \tag{8.3}$$

and the corresponding $U(1)$ actions can be read off from there. The last two D-terms serve to remove the redundancies inherent in (8.2). The first four D-terms correspond to the four $U(1)$'s of the quiver. Note that only three of these are independent. There is one constraint on the Fayet-Iliopoulos terms,

$$r_1 + r_2 + r_3 + r_4 = 0.$$

For, say $r_{1,2,3} > 0$, we can solve for $x, z, \tilde{x}$ in terms of $\tilde{z}$, and the moduli space is manifestly the line bundle over local F_0 , obtained by setting

$$\begin{aligned} |y|^2 + |w|^2 &= 2|\tilde{z}|^2 + r_1 - r_4 \\ |\tilde{y}|^2 + |\tilde{w}|^2 &= 2|\tilde{z}|^2 + r_1 + r_2 \end{aligned}$$

modulo the corresponding $U(1)$'s.

Consider now turning on a specific combination of Chern-Simons terms,

$$(k_1, k_2, k_3, k_4) = (0, k, 0, -k).$$

This corresponds to setting

$$r_2 \sim kr_0, \quad r_4 \sim -kr_0,$$

while the others are constant. We can use the second D-term in (8.3) to solve for r_0 , and the corresponding gauge symmetry,

$$\begin{aligned} \theta_0 &\rightarrow \theta_0 + k\lambda \\ x &\rightarrow xe^{-i\lambda} \\ \tilde{x} &\rightarrow \tilde{x}e^{i\lambda} \end{aligned} \tag{8.4}$$

to set θ_0 to zero. The first and the third D-term express x and z in terms of $\tilde{x}$ and $\tilde{z}$. The moduli space is thus

$$\begin{aligned} |y|^2 + |w|^2 &= |\tilde{x}|^2 + |\tilde{z}|^2 + r_1 + r_3 \\ |\tilde{y}|^2 + |\tilde{w}|^2 &= |\tilde{x}|^2 + |\tilde{z}|^2 \end{aligned}$$

modulo the corresponding $U(1)^2$ action. For $k = 1$, and $r_1 = 0 = r_2$, this gives a moduli space which is a cone over $Q^{1,1,1}$!

For general k , we still have to divide by the discrete gauge symmetry left over, corresponding to $\lambda = 2\pi i/k$ in (8.4). A symmetry under which x and $\tilde{x}$ transform as $(x, \tilde{x}) \rightarrow (e^{2\pi i/k} x, e^{-2\pi i/k} \tilde{x})$, while the rest of coordinates are neutral is gauge equivalent to one where $\tilde{x}$ and $\tilde{z}$ transform as

$$(\tilde{x}, \tilde{z}) \rightarrow (e^{2\pi i/k} \tilde{x}, e^{-2\pi i/k} \tilde{z}).$$

It is easy to see from above, that this corresponds to IIA string theory on $X_3 \times \mathbf{R}$ with

$$\int_{\mathbf{P}_1^1} F_{RR} = k, \quad \int_{\mathbf{P}_2^1} F_{RR} = k.$$

where to reproduce the Chern-Simons terms, an additional four-form flux must be turned on,

$$\int_{F_0} G_{RR} = k.$$

Note that despite the presence of the 4-form flux in IIA, there need not be any G -fluxes turned on in M-theory. This is because, just like in the previous section, there are monodromies acting on the cycles and fluxes as we go from positive to negative r_0 , under which

the 4-form flux transforms. The interpretation of this in the Calabi-Yau four-fold context is not clear to us.

In summary, IIA/M-theory duality predicts that the theory dual to the cone on $AdS_4 \times Q^{1,1,1}/\mathbf{Z}_k$ should be the $U(N)^4$ Chern-Simons theory corresponding to the quiver in figure 3 with superpotential (8.1), and Chern-Simons levels $(0, k, 0, -k)^{19}$. Since two of the Chern-Simons levels vanish, it is not obvious the theory has a weak coupling expansion at large k . The gauge fields associated to nodes 1 and 3 act as constraints, setting the corresponding currents to zero. Since this provides a very simple example of AdS/CFT correspondence, it would be nice to study this theory in detail. The theory may have a dual description in terms of Chern-Simons theories in [9,20], whose direct string theory realization we do not know.

9. N M2 branes on G_2 holonomy manifolds

In this section we conjecture a lagrangian description of N M2 branes probing a local G_2 holonomy manifold. For a single M2 brane, the corresponding low energy effective theory was proposed in [23]. We will explain here how this generalizes to arbitrary N . To begin with, consider IIA string theory compactified on a Calabi-Yau threefold X_3 . The theory has $\mathcal{N} = 2$ supersymmetry in the bulk. Turning on RR 2-form fluxes through the two-cycles of X_3 breaks supersymmetry to $\mathcal{N} = 1$ in four dimensions. The IIA string theory on X_3 with RR fluxes is dual M-theory on a G_2 holonomy manifold. We can get an explicit description of the G_2 holonomy manifold [23] along the lines of what we did in section two.

Consider again, as we did in section 2, a Calabi-Yau threefold described by a linear sigma model with $N + 4$ chiral fields ϕ_i and $N + 1$ $U(1)$ gauge fields with charges Q_i^a , $a = 0, \dots, N$. The Calabi Yau is the space of solutions to D-term equations

$$\sum_i Q_i^a |\phi_i|^2 = r_a, \quad a = 0, \dots, N$$

modulo the gauge transformations. Consider now turning on RR 2-form flux

$$[F_{RR}] = \sum_a k_a [D_a]$$

¹⁹ The quotient $Q^{1,1,1}/\mathbf{Z}_k$ is called $Y^{k,k}(\mathbf{P}^1 \times \mathbf{P}^1)$ in [4,22].

where D_a is a divisor corresponding to setting to zero a product of variables with charge 1 under the a -th $U(1)$, and zero under the rest. Type IIA string theory in this background should lift to a G_2 holonomy manifold in M-theory. It is easy to write down the corresponding G_2 manifold, at least topologically. The fluxes imply that the G_2 holonomy manifold is a non-trivial S^1 fibration over X_3 . Borrowing the results of section 2, the G_2 manifold is a Hopf-fibration: under the $U(1)^{N+1}$ gauge transformations that take

$$\phi_i \rightarrow \phi_i \exp(iQ_i^a \lambda_a)$$

the compact scalar θ_0 parameterizing the circle transforms as

$$\theta_0 \rightarrow \theta_0 + \sum_a k_a \lambda_a.$$

The difference with respect to section 2 is that the Calabi-Yau threefold is no longer fibered over $\mathbf{R}$ in a non-trivial way. This implies that the Calabi-Yau fourfold geometries of section 2 can also be viewed as G_2 holonomy fibrations over the real line. We'll return to this point below.

Consider now N D2 brane probing X_3 . As we reviewed in section 3, before turning on fluxes, in the limit where X_3 develops a singularity, the theory on the branes is an $\mathcal{N} = 2$ quiver gauge theory in three dimensions with superpotential. As we discussed in section 3, turning on RR fluxes turns on Chern-Simons terms on the D-branes. In fact, in the present context, they correspond to turning on $\mathcal{N} = 1$ Chern-Simons terms. This is because the fluxes break half the supersymmetry, so the theory on the branes with fluxes should have $\mathcal{N} = 1$ supersymmetry in three dimensions. This corresponds to deforming the action by

$$\int_{\mathbf{R}^{2,1}} d^3x \sum_{\alpha} k_{\alpha} S_{CS}(A_{\alpha})$$

where α denotes the nodes on the quiver, and

$$S_{CS}(A_{\alpha}) = \text{Tr } \omega_{CS}(A_{\alpha}) - \text{Tr } \bar{\chi}_{\alpha} \chi_{\alpha}$$

denotes the $\mathcal{N} = 1$ Chern-Simons term in the notation of [2]. The Chern-Simons levels get related to RR 2-form fluxes and the RR 4-form fluxes through the vanishing cycles, just as in the $\mathcal{N} = 2$ case, and moreover satisfy

$$\sum_{\alpha} k_{\alpha} = 0.$$

For a single brane probe, the center of mass gauge field on the D2 brane can be dualized to a compact scalar θ_0 parameterizing the position of the M2 brane on the M-theory circle. It is easy to see that, in the presence of $\mathcal{N} = 1$ Chern-Simons terms, the S^1 becomes fibered non-trivially over X_3 in such a way that the moduli space becomes $G_2 \times \mathbf{R}$.

For example, take X_3 to be the conifold, discussed in section 4. The theory on N D2 branes on X_3 is the Klebanov-Witten type quiver theory described there. Now consider turning on RR 2-form flux through the $\mathbf{P}^1$ of the conifold,

$$\int_{\mathbf{P}^1} F_{RR} = k,$$

but *not* fibering X_3 over $\mathbf{R}$, as we did there. This turns on $\mathcal{N} = 1$ Chen-Simons terms with $k_1 = k = -k_2$. Consider now the moduli space, for one D2 brane. The potential for σ 's vanishes for $\sigma_1 = r_0 = \sigma_2$ as before, but this no longer affects the FI terms. The D-term potential vanishes for

$$|A_1|^2 + |A_2|^2 - |B_1|^2 - |B_2|^2 = r \tag{9.1}$$

where $r_1 = r = -r_2$ is a constant Fayet-Iliopoulos term. We still need to divide by the gauge group. In the presence of the Chern-Simons coupling, the θ_0 scalar dual to the center of mass gauge field picks up a charge, so the gauge transformations act as

$$\begin{aligned} \theta_0 &\rightarrow \theta_0 + k\lambda \\ A_{1,2} &\rightarrow A_{1,2} e^{i\lambda} \\ B_{1,2} &\rightarrow B_{1,2} e^{-i\lambda}. \end{aligned}$$

We can use these to gauge away θ_0 , so the moduli space is a 7-manifold described by the locus (9.1) in $\mathbf{C}^4$ parameterized by $A_{1,2}$, and $B_{1,2}$. For $k = 1$, this is precisely the G_2 manifold discussed in [36]. For $k \neq 1$, we still have to divide this by the discrete gauge symmetry left over, generated by $\lambda = 2\pi/k$ so the manifold is a $\mathbf{Z}_k$ quotient. It is related by the "second" M-theory flop discovered in [37] to the $\mathbf{Z}_k$ actions considered in [36].

Similarly, for all other examples we wrote down in sections 5-8, we get pairs of G_2 manifolds and the corresponding $\mathcal{N} = 1$ quiver Chern-Simons theories. Namely, as we mentioned above, the Calabi-Yau fourfolds we studied in the $\mathcal{N} = 2$ context can be viewed as G_2 holonomy manifolds fibered over $\mathbf{R}$. Turning on RR fluxes in IIA, but *not* fibering the Calabi-Yau threefold over $\mathbf{R}$ corresponds to replacing the $\mathcal{N} = 2$ Chern-Simons couplings in sections 5-8 by $\mathcal{N} = 1$ Chern-Simons couplings. The type IIA/M theory duality then

relates this to N M2 branes on a G_2 holonomy manifold obtained by fixing a point in the base $\mathbf{R}$ of the corresponding Calabi-Yau four-fold X_4 . Moreover, the RR 2-form fluxes are geometrized in M-theory, but RR 4-form fluxes become G -fluxes on the G_2 manifold.

String duality now implies that, in the IR, the theory on N D2 branes in these IIA backgrounds becomes the theory on N M2 branes probing the corresponding G_2 holonomy manifolds. Since the gauge kinetic terms vanish in this limit, the theory should naturally become the $\mathcal{N} = 1$ quiver Chern-Simons theory. This provides a Lagrangian description of the low energy theory on the N M2 branes probing a G_2 holonomy manifold. Note that there are no known Einstein manifolds which are cones over G_2 holonomy manifolds times $\mathbf{R}$ [21], so we don't expect these theories to flow to conformal field theories in three dimensions. It will be interesting to see if some insights into the dynamics of these theories could still be obtained.

Acknowledgments

We would like to thank C. Beem and Y. Nakayama for fruitful discussions, and collaboration on an earlier related project. We are also grateful to O. Ganor for valuable discussions. We thank C. Vafa for collaboration on [23] which was crucial for this paper. The author is indebted to A. Hanany for a beautiful talk at BCTP which initiated this work, and discussions at the early stage of the project.

The research of M.A. is supported in part by the UC Berkeley Center for Theoretical Physics and the NSF grant PHY-0457317.
